

11.9.3 The Abstract Equality Comparison Algorithm

The comparison `x == y`, where `x` and `y` are values, produces **true** or **false**. Such a comparison is performed as follows:

1. If `Type(x)` is the same as `Type(y)`, then
 - a. If `Type(x)` is **Undefined**, return **true**.
 - b. If `Type(x)` is **Null**, return **true**.
 - c. If `Type(x)` is **Number**, then
 - i. If `x` is **NaN**, return **false**.
 - ii. If `y` is **NaN**, return **false**.
 - iii. If `x` is the same **Number** value as `y`, return **true**.
 - iv. If `x` is **+0** and `y` is **-0**, return **true**.
 - v. If `x` is **-0** and `y` is **+0**, return **true**.
 - vi. Return **false**.
 - d. If `Type(x)` is **String**, then return **true** if `x` and `y` are exactly the same sequence of characters (same length and same characters in corresponding positions). Otherwise, return **false**.
 - e. If `Type(x)` is **Boolean**, return **true** if `x` and `y` are both **true** or both **false**. Otherwise, return **false**.
 - f. Return **true** if `x` and `y` refer to the same object. Otherwise, return **false**.
2. If `x` is **null** and `y` is **undefined**, return **true**.
3. If `x` is **undefined** and `y` is **null**, return **true**.
4. If `Type(x)` is **Number** and `Type(y)` is **String**, return the result of the comparison `x == ToNumber(y)`.
5. If `Type(x)` is **String** and `Type(y)` is **Number**, return the result of the comparison `ToNumber(x) == y`.
6. If `Type(x)` is **Boolean**, return the result of the comparison `ToNumber(x) == y`.
7. If `Type(y)` is **Boolean**, return the result of the comparison `x == ToNumber(y)`.
8. If `Type(x)` is either **String** or **Number** and `Type(y)` is **Object**, return the result of the comparison `x == ToPrimitive(y)`.
9. If `Type(x)` is **Object** and `Type(y)` is either **String** or **Number**, return the result of the comparison `ToPrimitive(x) == y`.
10. Return **false**.

NOTE 1 Given the above definition of equality:

- String comparison can be forced by: `" " + a == " " + b`.
- Numeric comparison can be forced by: `+a == +b`.
- Boolean comparison can be forced by: `!a == !b`.

NOTE 2 The equality operators maintain the following invariants:

- `A != B` is equivalent to `!(A == B)`.
- `A == B` is equivalent to `B == A`, except in the order of evaluation of `A` and `B`.

NOTE 3 The equality operator is not always transitive. For example, there might be two distinct **String** objects, each representing the same **String** value; each **String** object would be considered equal to the **String** value by the `==` operator, but the two **String** objects would not be equal to each other. For Example:

- `new String("a") == "a"` and `"a" == new String("a")` are both **true**.
- `new String("a") == new String("a")` is **false**.

NOTE 4 Comparison of **Strings** uses a simple equality test on sequences of code unit values. There is no attempt to use the more complex, semantically oriented definitions of character or string equality and collating order defined in the Unicode specification. Therefore **Strings** values that are canonically equal according to the Unicode standard could test as unequal. In effect this algorithm assumes that both **Strings** are already in normalised form.

11.9.6 The Strict Equality Comparison Algorithm

The comparison `x === y`, where `x` and `y` are values, produces **true** or **false**. Such a comparison is performed as follows:

1. If `Type(x)` is different from `Type(y)`, return **false**.
2. If `Type(x)` is **Undefined**, return **true**.
3. If `Type(x)` is **Null**, return **true**.
4. If `Type(x)` is **Number**, then
 - a. If `x` is **NaN**, return **false**.
 - b. If `y` is **NaN**, return **false**.
 - c. If `x` is the same **Number** value as `y`, return **true**.
 - d. If `x` is **+0** and `y` is **-0**, return **true**.
 - e. If `x` is **-0** and `y` is **+0**, return **true**.
 - f. Return **false**.
5. If `Type(x)` is **String**, then return **true** if `x` and `y` are exactly the same sequence of characters (same length and same characters in corresponding positions); otherwise, return **false**.
6. If `Type(x)` is **Boolean**, return **true** if `x` and `y` are both **true** or both **false**; otherwise, return **false**.
7. Return **true** if `x` and `y` refer to the same object. Otherwise, return **false**.

NOTE This algorithm differs from the `SameValue` Algorithm (9.12) in its treatment of signed zeroes and NaNs.
